What We Actually
Do

Vertical axis:

- Prediction with expert advice: $L_1(x_{1:t}) - L_2(x_{1:t})$
- Hypothesis testing: $\log(P_1(x_{1:t})/P_0(x_{1:t}))$
- The logarithm of a stock price.

What We Actually
Do

Vertical axis:

- Prediction with expert advice: $L_1(x_{1:t}) - L_2(x_{1:t})$
- Hypothesis testing: $\log(P_1(x_{1:t})/P_0(x_{1:t}))$
- The logarithm of a stock price.

Goal: predict whether the line will go up or down.

Switching

What We Actually
Do

A basic investment strategy σ_t is to sell at a predetermined time t .

Problem: *in hindsight* we know when the oil started leaking!

Hedging

What We Do

All About A Line
Basic Investment
Strategies

Hedging

Price Switched
Strategies

More Price
Switching

What We Actually
Do

We distribute initial capital over $\sigma_1, \dots, \sigma_T$.

Let $\pi(t)$ denote the fraction of capital assigned to strategy σ_t .

Let $\Lambda(0) = 0$. We obtain payoff:

$$\log \sum_{t=0}^T e^{\Lambda(t)} \pi(t) \geq \log \left(e^{\Lambda(\hat{t})} \pi(\hat{t}) \right) = \Lambda(\hat{t}) - (-\log \pi(\hat{t})).$$

What We Actually
Do

We distribute initial capital over $\sigma_1, \dots, \sigma_T$.

Let $\pi(t)$ denote the fraction of capital assigned to strategy σ_t .

Let $\Lambda(0) = 0$. We obtain payoff:

$$\log \sum_{t=0}^T e^{\Lambda(t)} \pi(t) \geq \log \left(e^{\Lambda(\hat{t})} \pi(\hat{t}) \right) = \Lambda(\hat{t}) - \underbrace{(-\log \pi(\hat{t}))}_{\text{regret}}.$$

Regret may be relatively large or small, depending on

- How much the stock price drops
- The granularity of measurement

What We Actually
Do

We distribute initial capital over $\sigma_1, \dots, \sigma_T$.

Let $\pi(t)$ denote the fraction of capital assigned to strategy σ_t .

Let $\Lambda(0) = 0$. We obtain payoff:

$$\log \sum_{t=0}^T e^{\Lambda(t)} \pi(t) \geq \log \left(e^{\Lambda(\hat{t})} \pi(\hat{t}) \right) = \Lambda(\hat{t}) - \underbrace{(-\log \pi(\hat{t}))}_{\text{regret}}.$$

Regret may be relatively large or small, depending on

- How much the stock price drops
- The granularity of measurement ← undesirable!

Price Switched Strategies

What We Do

All About A Line
Basic Investment
Strategies

Hedging

Price Switched
Strategies

More Price
Switching

What We Actually
Do

We parameterised the strategy to sell by time $t \dots$

Let us now define σ_p to sell when $\Lambda(t) \geq p$.

- Time-switched strategy: decision to sell depends on t
- Price-switched strategy: decision to sell depends on $\Lambda(t)$

Price Switched Strategies

Strategies

More Price
Switching

What We Actually
Do

We parameterised the strategy to sell by time t ...

Let us now define σ_p to sell when $\Lambda(t) \geq p$.

- Time-switched strategy: decision to sell depends on t
- Price-switched strategy: decision to sell depends on $\Lambda(t)$

We can no longer sell at every moment. But that's OK.

What We Do

All About A Line
Basic Investment
Strategies

Hedging
Price Switched
Strategies

More Price
Switching

What We Actually
Do

We can hedge as before to obtain at least

$$\log \sum_{p=0}^{\hat{p}} e^p \pi(p) \geq \log \left(e^{\hat{p}} \pi(\hat{p}) \right) = \hat{p} - (-\log \pi(\hat{p})).$$

For sufficiently large \hat{p} , the regret is relatively small!

What We Actually Do

Continuous Price

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Actually, logprices are not integers and we do not pretend they are.

We can get very close to the previous bound:
if π is a decreasing density on the positive reals, then

$$\log \int_0^{\hat{p}} e^p \pi(p) dp \geq \log \left(\pi(\hat{p}) \int_0^{\hat{p}} e^p dp \right) = \log(e^{\hat{p}} - 1) - (-\log \pi(\hat{p})).$$

We cannot sell at \hat{p} exactly anymore \rightarrow small additional overhead

Multiple Switches

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Actually, we are interested in exploiting multiple switches.

Let $\delta = (\delta_1, \delta_2, \dots)$. A strategy σ_δ :

- initially invests all capital
- sells all stock when the logprice goes up δ_1 or more, then
- invests all capital again as it goes down δ_2 or more,
- etcetera.

Continuous Time

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Intuition: Discontinuities in Λ are helpful.

Continuous Time

What We Do

What We Actually Do

Continuous Price
Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Intuition: Discontinuities in Λ are helpful.

Let the logprice function be $\Lambda : [0, T] \rightarrow \mathbb{R}$.

A discrete time scenario can be modelled by a step function.

Theorem 1 *The payoff of our strategy decreases when a discontinuity in the logprice function is replaced by a continuous monotonic transition.*

Continuous Time

What We Do

What We Actually Do

Continuous Price
Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Intuition: Discontinuities in Λ are helpful.

Let the logprice function be $\Lambda : [0, T] \rightarrow \mathbb{R}$.

A discrete time scenario can be modelled by a step function.

Theorem 1 *The payoff of our strategy decreases when a discontinuity in the logprice function is replaced by a continuous monotonic transition.*

- We can simplify the analysis by assuming continuity.

Monotonicity

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Intuition: The more fluctuations in Λ , the better.

Monotonicity

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Intuition: The more fluctuations in Λ , the better.

Theorem 2 *Fix the value of Λ at arbitrary times $0 = t_1 < \dots < t_m = T$. Our strategy achieves minimal payoff if the successive intervals of Λ are monotone.*

Monotonicity

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Intuition: The more fluctuations in Λ , the better.

Theorem 2 *Fix the value of Λ at arbitrary times $0 = t_1 < \dots < t_m = T$. Our strategy achieves minimal payoff if the successive intervals of Λ are monotone.*

In summary, the regret compared to a specific δ is maximised if

- Λ is continuous (Thm 1)
- Λ is monotonic in-between switches (Thm 2)

The worst case regret is realised in the ideal case for analysis!

Regret Bound

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Theorem 3 *Given any Λ and a basic strategy δ that performs its m th switch on Λ at time T . The payoff of our strategy is at least*

$$\sum_{1 \leq \text{odd } i \leq m} \delta_i - \left(\sum_{i=1}^m -\log \pi(\delta_i) + (m-1)c_\pi + \ln 2 + 2\epsilon_\pi \right).$$

Here, c_π and ϵ_π are small constants that depend on π ; values are typically around 0.02 and 3.5, respectively.

Regret Bound

What We Do

What We Actually Do

Continuous Price

Multiple Switches

Continuous Time

Monotonicity

Regret Bound

Example

Algorithm

Theorem 3 Given any Λ and a basic strategy δ that performs its m th switch on Λ at time T . The payoff of our strategy is at least

$$\sum_{1 \leq \text{odd } i \leq m} \delta_i - \left(\sum_{i=1}^m -\log \pi(\delta_i) + (m-1)c_\pi + \ln 2 + 2\epsilon_\pi \right).$$

Here, c_π and ϵ_π are small constants that depend on π ; values are typically around 0.02 and 3.5, respectively.

Thus,

- Small fluctuations are hard to exploit
- The bound is best applied to parsimonious strategies (with small m)

Monotonicity
Regret Bound

Example

Algorithm

Strategy	Payoff
Invest everything	90
Ideal	1021
Model	178
Bound	105
Actual performance	175

- Performance on real stock: probably not brilliant
- Strategy still useful as a safeguard against excessive loss

Example

What We Do

What We Actually Do

Continuous Price
Multiple Switches
Continuous Time
Monotonicity
Regret Bound

Example

Algorithm

Strategy	Payoff
Invest everything	90
Ideal	1021
Model	178
Bound	105
Actual performance	175

- Performance on real stock: probably not brilliant
- Strategy still useful as a safeguard against excessive loss
- In other applications Λ is usually less adversarial
- Performance is competitive with Fixed Share and typically better than Variable Share for log loss.
